RESEARCH INSTITUTE

Note that in this discussion “generation” refers to energy, for example in GWh, and “capacity” refers to the ability of generators to supply power, for example in GW. Both are scaled to the number of vehicles, based on the numbers in slide 14. Note that there are many reasons that these national figures for generation and capacity would not be available to every customer in every location; they are meant to convey the order-of-magnitude.

Impacts per vehicle

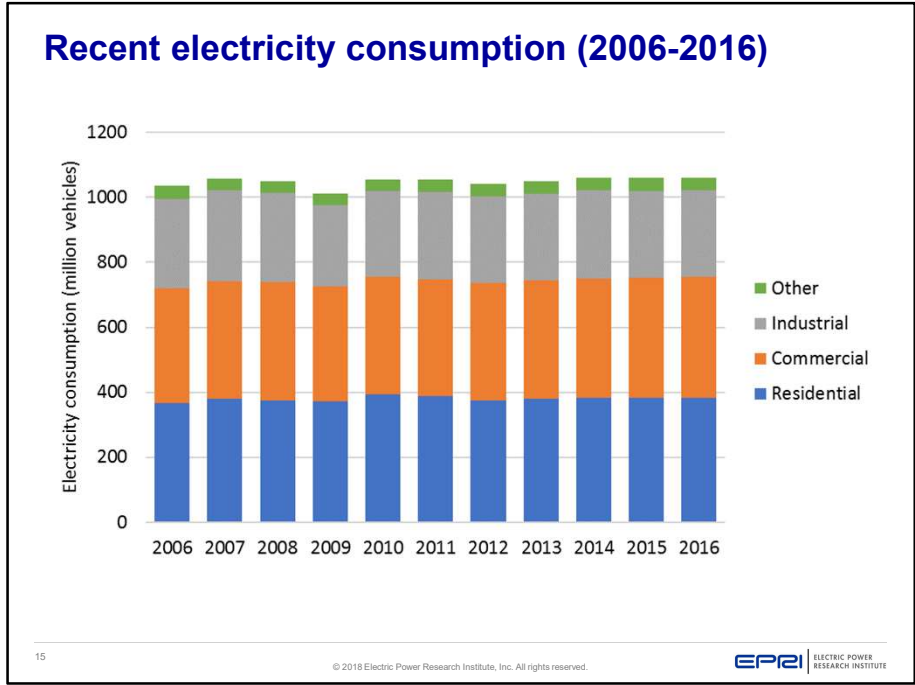

- An average PEV has a power impact of about 1 kW and an energy impact of about 3000 kWh/year

14

EPRI | ELECTRIC POWER RESEARCH INSTITUTE

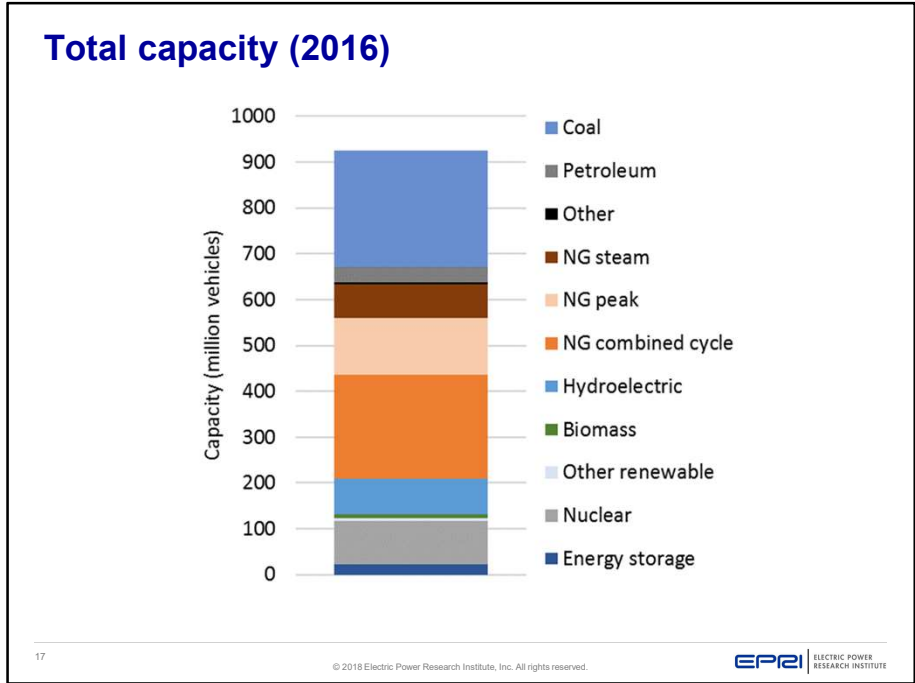

EPRI analysis of western utility; although no time-of-use variation was in place for this rate, many people still waited until after midnight to charge.

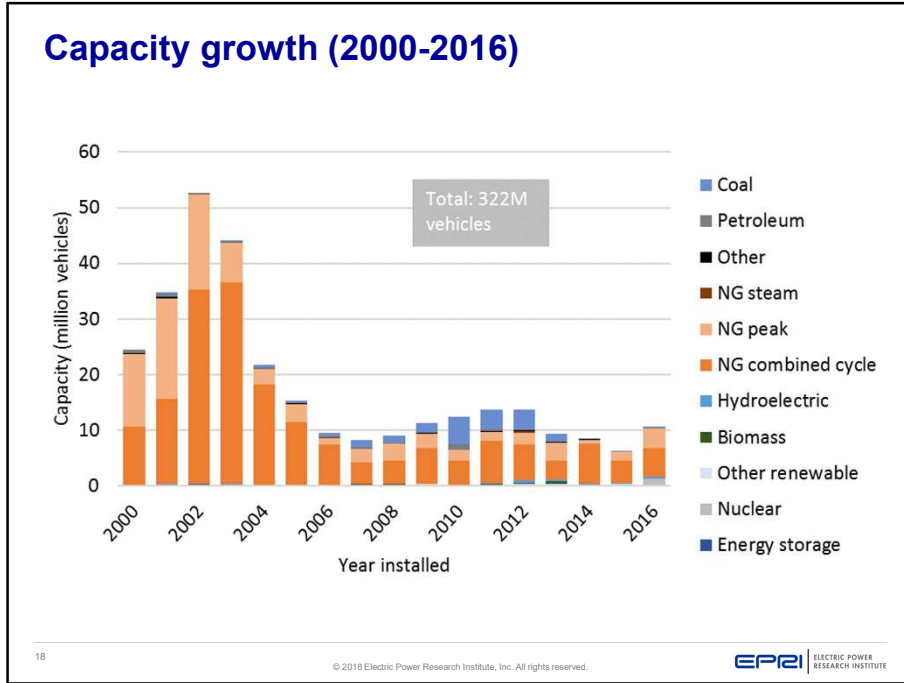

The US generates enough electricity to fuel 1 billion cars at current vehicle efficiency levels.
 EIA data (with scaling)

In the past 10 years there has been little growth in generation, but historically there have been sustained periods of time when the grid added 25 million vehicles worth of generation *per year*. EIA data (with scaling)

The US also has capacity equivalent to about 900 million vehicles (note that intermittent renewables are excluded from this). EIA data (with scaling)

In the past 16 years, the US has added about 10M-50M vehicles worth of capacity per year (note that intermittent renewables are excluded from this). EIA data (with scaling)

Residential distribution impacts

- Sacramento Municipal Utility District analysis of distribution impacts

EPR | ELECTRIC POWER RESEARCH INSTITUTE

For the same number of vehicles, scenarios with high power incurred much higher costs than those with less power. Delaying charging till midnight helped in most situations. Note that what is good for the distribution system may not be good for generation capacity and vice-versa. For more information see “SMUD’s EV Innovators Pilot - Load Impact Evaluation”: <https://www.smud.org/-/media/About-Us/Research-and-Development/Energy-Research-and-Development/research-EV-innovators.ashx?la=en&hash=AC5E4B8ED85279926EBF59B54E41426FFE79F29A>

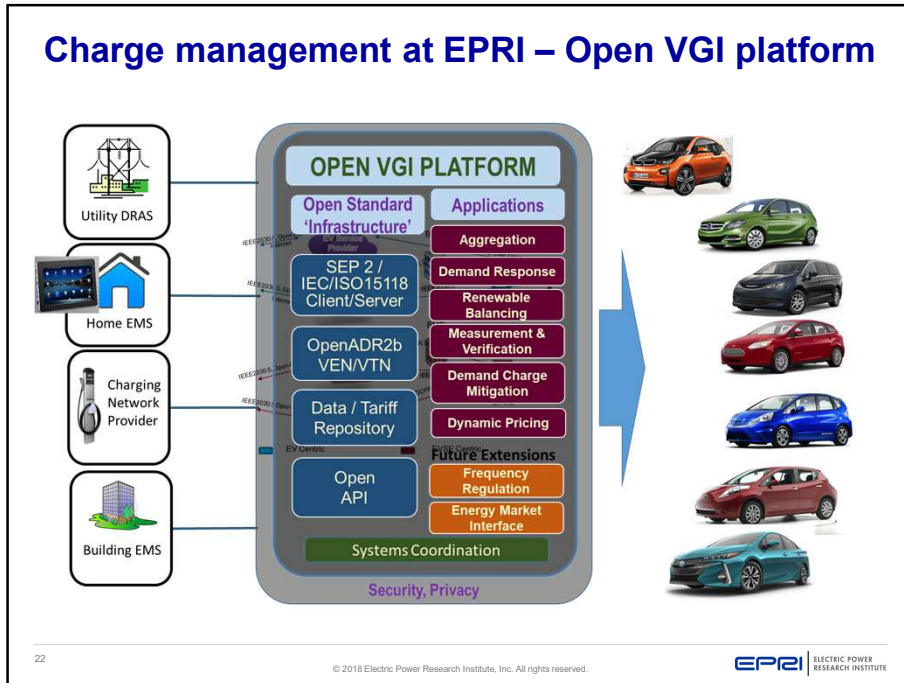

Can we be smarter?

That was the “big iron” solution; how about using intelligence to mitigate problems?

Options to improve

- Charge management
 - Time of use rate
 - Direct signaling
- Demand response
- Vehicle-to-grid

Charge management at EPRI – Open VGI platform

Open VGI is meant to be a “Rosetta Stone” to allow different upstream communication protocols and methodologies to interface with different vehicle ones, while ensuring end-to-end security.

Vehicle-to-grid at EPRI – Smart Power Integrated Node (SPIN)

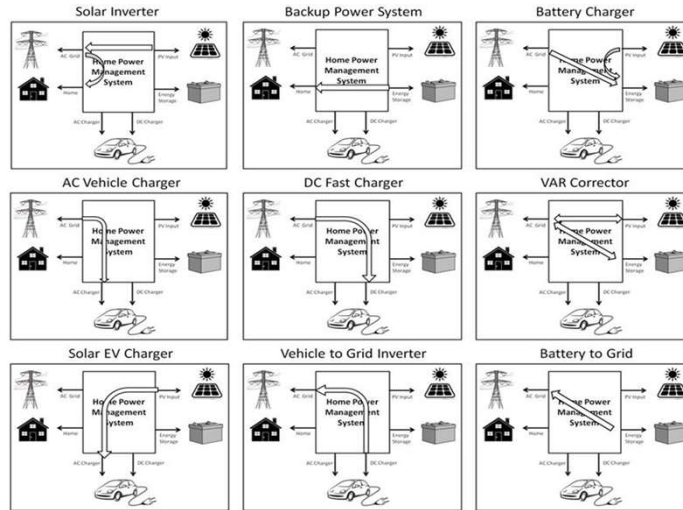

23

EPRI | ELECTRIC POWER RESEARCH INSTITUTE

SPIN is a specific devices being developed to act as a smart inverter to route power between advanced energy products, particularly those using DC power. The project includes funding and involvement from DOE and CEC.

SPIN Operating Modes / Scenarios
